PREFACE

This report has been prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the spillway design flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. The spillway design flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I REPORT

NATIONAL DAM INSPECTION PROGRAM

BRIEF ASSESSMENT OF GENERAL CONDITIONS AND RECOMMENDATIONS

Name of Dam:

LEWIS LAKE DAM

State & State No.:

PENNSYLVANIA, 58-7

County:

SUSQUEHANNA

Stream:

FIDDLE LAKE CREEK

Date of Inspection:

May 7, 1980

Based on the visual inspection, past performance and the available engineering data, the dam and its appurtenant structures appear to be in fair condition.

In accordance with the Corps of Engineers' evaluation guidelines, the size classification of this dam is small and the hazard classification is high. These classifications indicate that the Spillway Design Flood (SDF) should be in the range of one-half the Probable Maximum Flood (PMF) to the full PMF. The recommended SDF for this structure is one-half the PMF. The spillway capacity is adequate for passing only 10 percent of the PMF peak inflow without overtopping the dam. The spillway is considered to be seriously inadequate. The dam is therefore unsafe, non-emergency. A

The following recommendations are presented for immediate action by the owner:

- 1. That a detailed hydrologic and hydraulic engineering analysis be made by a professional engineer with experience in the design and construction of dams to determine means for improving the capacity of the spillway and reservoir system so that it will meet the requirements of the Commonwealth of Pennsylvania.
- 2. That all brush and trees be removed from the embankment slopes and in an area 10 feet beyond the downstream toe of the embankment, and that a professional engineer be consulted regarding removal of the tree stumps and root systems.

- 3. That the deteriorated areas on the downstream masonry portion of the dam be repaired.
- 4. That the deteriorated areas of the spillway abutments be repaired, and that the forebay area be cleared of obstructing fi11.
- 5. That a formal surveillance and downstream warning system be developed for use during periods of high or prolonged rainfall.
- 6. That an operation and maintenance manual be prepared for guidance in the operation of the dam during normal and emergency conditions, and that a schedule be developed for the annual inspection of the dam and its appurtenant structures.

> LEWIS LAKE DAM humber

(NDI-ID N. PA-00061, DER-ID 58-7)

River Baily, Susquehanna County, Pennsylvace. V

(15) DACW31-89-C- \$\$19

1.1 GENERAL

Authority

(10) Handrik / Jon ... The Dam Inspection Act, Public Law 92-367, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a program of inspections of dams throughout the United States.

В. Purpose

The purpose is to determine if the dam constitutes a hazard to human life and property.

1.2 DESCRIPTION OF PROJECT

Α. Description of Dam and Appurtenances

Note:

Normal pool level is estimated at Elev. 1710.0 from the U.S.G.S. quadrangle map. This elevation is used as top of spillway elevation in this report. Construction drawings indicate top of spillway elevation at Elev. 95.5.

Lewis Lake Dam is an earth and masonry structure having dry rubble masonry on the downstream side of the embankment and earthfill on the upstream side. The height of the embankment is 15 feet and the length is 186 feet. A double row of wooden sheet piling was driven into the earth portion of the embankment. A concrete cutoff was installed upstream of the spillway, and concrete retaining walls were installed at the spillway abutments.

The spillway is located near the center of the embankment and is on two levels. The lower level is 19 feet long and has a pier and slots for stoplog installation. The upper level is to the left of the lower level and is about 41 feet long. A sluiceway, located to the right of the spillway, has been plugged with concrete.

B. Location:

Herrick Township, Susquehanna County U.S.G.S. Quadrangle - Forest City, Pa. Latitude 41°-43.0', Longitude 75°-29.8' Appendix E, Plates I & II

C. Size Classification:

Small: Height - 15 feet Storage - 977 acre-feet

D. Hazard Classification:

High (Refer to Section 3.1.E.)

E. Ownership:

R.C. Panuska, Treasurer Lewis Lake Association, Inc. R.D. #1, Box 203 Union Dale, PA 18407

F. Purpose:

Recreation

G. Design and Construction History

The dam was built by David Lewis, owner of the dam, in about 1835 as a mill dam. In 1876 the dam was raised by 2 feet and flashboards were installed by the Erie Railway Company in return for water rights. In 1917, the wooded sheet piling was installed, and the spillway was enlarged to its present size. The elevation of the spillway was not raised, but the embankment was raised, and the original timber sluiceway was replaced with a concrete structure. In 1929, the wooden planking that was used for the spillway was replaced with a concrete slab. Concrete retaining walls and a concrete cutoff wall upstream of the spillway were built at that time to replace a portion of deteriorated timber sheet piling. Over the years, a considerable amount of fill has been placed on the embankment to fill areas where settlement has occurred. In 1975 the sluiceway was filled with concrete and a large amount of fill mixed with clay was placed on the embankment and upstream slope to reduce leakage through the downstream wall. This leakage has been reported since 1913.

No information is available on the original design; Plates III and IV in Appendix E show modifications made in 1917 and 1929 respectively.

H. Normal Operating Procedures

The reservoir is used for recreation and all inflow is discharged over the spillway. There are no operating procedures.

1.3 PERTINENT DATA

	Type: Earthfill with dry rubble masonry.	
	Length: 186 feet.	
	Height: 15 feet.	

Top Width: 18 feet.

Side Slopes: Survey:

Upstream - Varies. Downstream - 1H to 4V

Zoning: Dry rubble masonry on downstream side.

Cutoff: Wooden sheet piling over entire length. Concrete cutoff upstream of spillway.

Grouting: None.

H. Outlet Facilities

None.

I. Spillway

Type: Broad crested weir at two levels. Lower level has slots for stoplog installation.

Length: Lower Level - 19 feet.

Upper Level - 41 feet.

Crest Elevation: Lower Level - 1710

Upper Level - 1711.7

Location: Center of dam.

J. Regulating Outlet

None.

SECTION 2 - ENGINEERING DATA

2.1 DESIGN

The engineering design data for Lewis Lake Dam are limited to the design drawings prepared by the Erie Railway Company for modifications done in 1917 and 1929. Embankment stability or hydraulic calculations are not available for review.

2.2 CONSTRUCTION

The dam was constructed in about 1835 and modified in 1876 and 1975. There are no records for these periods of construction. Modifications were also made in 1917 and 1929. For these construction periods, progress reports by a state inspector are available in the Pennsylvania Department of Environmental Resources (PennDER) files, along with a set of specifications for the work done in 1917.

2.3 OPERATION

Records of operation have not been maintained by the owner. The PennDER files included copies of previous inspection reports dating back to 1913. Seepage has been reported as a continuing problem. The largest amounts of seepage have occurred to the right of the spillway, and settlement of the embankment adjacent to the sluiceway has been attributed to this seepage. Smaller amounts of seepage were reported to have occurred to the left of the spillway. Trees and brush have not been removed regularly from the embankment. The reservoir was originally used for supplying water to a feed mill, a lumber mill and the Erie Railway. The use by these industries was discontinued many years ago.

2.4 EVALUATION

A. Availability

The available engineering data is contained in the files of PennDER, Harrisburg, Pennsylvania.

B. Adequacy

The available engineering and construction data, combined with the field inspection, are considered to be adequate for making a reasonable assessment of the dam.

C. Operating Records

Operating records, including maximum pool levels, have not been maintained.

D. Post Construction Changes

Post construction changes have included raising the dam by two feet and installing flashboards in 1876; modifying the spillway and sluiceway and raising the embankment in 1917; installing concrete cutoff walls, retaining walls and slab on the spillway in 1929; and plugging the sluiceway with concrete and placing an earth and clay blanket on the upstream embankment slope in 1975.

SECTION 3 - VISUAL INSPECTION

3.1 FINDINGS

A. General

The general appearance of Lewis Lake Dam is fair. The condition can be improved with some regular maintenance work. The spillway, located near the center of the dam, is in fair condition except for the presence of some fill acting as an obstruction in the forebay area and on the upper level of the spillway. The embankment appears to be stable but there is a growth of heavy weeds, small trees and brush on the right embankment. Seepage was not detected.

The visual inspection check list and sketches of the general plan and profile of the dam, as surveyed during the inspection, are presented in Appendix A of this report. Photographs of the facilities taken during the inspection are reproduced in Appendix C.

B. Embankment

The horizontal alignment of the embankment is good. The embankment curves upstream slightly at both abutments. The vertical profile of the dam (Plate A-II, Appendix A), indicates that the crest of the dam is above design elevation except adjacent to the spillway walls.

The embankment is protected with a grass mat on the crest and the upstream slope. There is no riprap protection on the upstream slope. The downstream slope is a near vertical masonry wall. The right end of the embankment has some high weeds, brush and small trees growing from it.

Settlement of the embankment has occurred on the right side of the spillway creating a low area. Some of the stone was displaced from the wall on the downstream side. At the center of the dam, the downstream toe was submerged by tailwater from Fiddle Lake Creek; however, no seepage was noticed coming from the embankment.

C. Appurtenant Structures

The concrete, broad crested spillway is located near the center of the dam. The spillway is on two levels. The lower level has a pier and slots for the installation of stoplogs. The downstream end of the spillway consists of a vertical drop to the natural streambed. The fill which was placed on the upstream slope of the embankment has extended across the spillway approach. This has broadened the crest of the spillway. Over a portion of the upper level spillway crest, the fill extends above the level of the concrete and acts to obstruct flow over the spillway.

The sluiceway, which is located to the right of the spillway, has been plugged with concrete.

D. Reservoir Area

The reservoir is surrounded by woodlands on moderate slopes. Many homes and cottages are located around the lake. The banks are stable. Two other reservoirs are located upstream from Lewis Lake (Plate D-1, Appendix D).

E. Downstream Channel and Area

The immediate downstream channel has a rocky bottom and is relatively wide and flat. About 850 feet downstream is the Borough of Union Dale where one house lies adjacent to the stream banks, and an industrial building has been built over the channel. A potential hazard to loss of life exists if the dam fails. The hazard category is considered to be "High."

3.2 EVALUATION

The overall visual evaluation of the facilities indicates that the dam in in fair condition, mostly as the result of poor maintenance practices. Recommendations include the removal of brush and trees from the embankment, removal of the obstructing fill from the spillway crest, and repair of the deteriorated downstream masonry portion of the dam.

SECTION 4 - OPERATIONAL PROCEDURES

4.1 PROCEDURES

The dam and reservoir were constructed for use as a mill pond, but have since become a recreational facility. The reservoir is maintained at the normal pool level (top of spillway). All inflow is discharged over the spillway.

4.2 MAINTENANCE OF DAM

The left end of the embankment has a good grass mat, few weeds and appears to be moved regularly. The right end of the embankment has a heavy growth of weeds, brush and some small trees on the crest and upstream slope.

4.3 MAINTENANCE OF OPERATING FACILITIES

There are no operating facilities for this dam.

4.4 WARNING SYSTEM

There is no formally organized surveillance and downstream warning system in existence at the present time.

4.5 EVALUATION

Operational procedures for Lewis Lake Dam do not exist at the present time. It is recommended that a program be developed for regular maintenance of the dam, which should include the removal of weeds and brush and the clearing of the spillway forebay area. A formal surveillance plan and downstream warning system should be developed for implementation during periods of heavy or prolonged precipitation.

SECTION 5 - HYDROLOGY/HYDRAULICS

5.1 EVALUATION OF FEATURES

A. Design Data

The hydrologic and hydraulic analyses available from PennDER for Lewis Lake Dam were not very extensive. No stage-discharge curve, stage-storage curve, unit hydrograph, or flood routings were contained in the PennDER files.

B. Experience Data

It was reported that the maximum known flood at Lewis Lake Dam occurred in June, 1972, when the water level in the lake reached an elevation about three feet higher than the spillway crest. This flood event was passed without reported damage.

C. Visual Observations

On the date of the inspection, no conditions were observed that would indicate that the appurtenant structures of the dam could not operate satisfactorily during a flood event until the dam is overtopped. It was noted that the outlet sluiceway has been filled in with concrete, eliminating drawdown capability. Upstream of Lewis Lake is one manmade dam and one natural lake. These impoundments were included in the hydrologic evaluation in Appendix D.

D. Overtopping Potential

Lewis Lake has a total storage capacity of 977 acre-feet and an overall height of 15 feet, both referenced to the top of the dam. These dimensions indicate a size classification of "Small," the hazard classification is "High" (see Section 3.1.E.).

The recommended Spillway Design Flood (SDF) for a dam having the above classification is in the range of one-half the Probable Maximum Flood (PMF) to the full PMF. Because of the size, the recommended SDF is one-half the PMF. For this dam, the SDF peak inflow is 5508 cfs (see Appendix D for HEC-l inflow computations).

Comparison of the estimated SDF peak inflow of 5508 cfs with the estimated spillway discharge capacity of 825 cfs indicates that a potential for overtopping of Lewis Lake exists.

An estimate of the storage effect of the reservoir and routing of the computed inflow hydrograph through the reservoir shows that this dam does not have the necessary storage available to pass the SDF without

overtopping. The spillway-reservoir system can pass a flood event equal to 10% of a PMF.

E. Dam Break Evaluation

The calculations to determine the behavior of the dam in the event of an overtopping and a resulting breaching of the embankment indicates that there will be a substantial increase in water levels downstream from the dam.

Several houses are located in Union Dale about 850 feet downstream from the dam. On the basis of the results of the dam break analysis, using the U.S. Army Corps of Engineers HEC-1 program, the water surface elevations in the vicinity of the houses have been compared for several conditions prior to and after a dam break. (Refer to Table 1, Appendix D). For an earth embankment, it is estimated that one-half foot of overtopping would result in a breach. Calculations indicate that 13 percent of the PMF inflow would cause an overtopping of 0.5 foot. The increase in water levels downstream due to overtopping of 0.5 foot with no failure as compared to no overtopping would be 0.5 foot. While more property would be exposed to flooding, the increase in the hazard to loss of life is not considered significant. With failure, however, the breaching analysis indicates a rise of 5.8 feet above the flow level just prior to breach when considering a 15 minute time to complete the breach and a 3.3 foot rise above flow level just prior to breach when considering a two hour time to complete the breach. The increase in hazard to loss of life and property damage is reflected not only in the increase in depth of water of 5.8 feet in the 15 minute breach and 3.3 feet in the two hour breach, but more significantly in the shorter time to reach the peak. Less time would be available to respond to the flooding under the breach conditions.

Being an earth embankment, it is judged that the breach would be completed between the 15 minute and the two hour period. The numerical difference of water levels is 2.5 feet. The property damage would be similar with either time of failure. Again, however, the time factor is most significant regarding loss of life. Calculations indicate that the water depth will increase at a rate of 5.8 feet in 15 minutes under the 15 minute breach condition.

One manmade dam and one natural lake are located upstream of Lewis Lake Dam. This upstream dam overtops with 13% of a PMF; however, the overtopping occurs on natural ground at the abutment and is not expected to cause failure. For this evaluation, neither of the impoundments were considered to have breached (see Appendix D).

On the basis of these calculations, it is concluded that the hazard to loss of life and property damage is significantly increased when the dam is overtopped and failed as compared to the condition just prior to failure.

Refer to Table 1, Appendix D, for comparison of flood water levels.

F. Spillway Adequacy

The small size category and high hazard category, in accordance with the Corps of Engineers criteria and guidelines, indicates that the SDF for this dam should be in the range of one-half the PMF to the full PMF. The recommended SDF is one-half PMF.

Calculations show that the spillway discharge capacity and reservoir storage capacity combine to handle 10% of the PMF (refer to Appendix D).

Since the spillway discharge and reservoir storage capacity cannot pass one-half of the PMF and because the downstream hazard to loss of life is high and this hazard is significantly increased when the dam fails as compared to just prior to failure, the spillway is judged to be seriously inadequate.

The hydrologic analysis for this investigation was based upon existing conditions of the watershed. The effects of future development were not considered.

SECTION 6 - STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

A. Visual Observations

1. Embankment

The visual inspection of Lewis Lake Dam indicates that the slopes are apparently stable. The upstream slope is protected with a grass mat cover to the water's edge. No riprap was used for protection. No sloughage or cracking was noticed. The downstream side is a nearly vertical, dry rubble masonry wall. Some of the stones have been displaced. No buldging was noticed. The profile of the dam indicates that the crest is above design elevation with the exception of a low area to the right of the spillway. No seepage was noticed during the visual inspection. The root system of the trees on the embankment could cause stability or seepage problems and should be removed.

2. Appurtenant Structures

The concrete spillway is in fair condition. Fill had been placed on the upstream slope of the embankment and some of this fill had been placed on top of the upper level spillway crest. At the right abutment of the spillway is the sluiceway structure. The concrete is cracked and deteriorating. Some patching of this concrete has taken place. On the top of the old sluiceway structure considerable spalling has occurred.

B. Design and Construction Data

Records of design and construction were not available for review, with the exception of data on the modifications which took place in 1917 and 1929.

C. Operating Records

There are no formal operating records for this dam. Previous inspection reports indicate that seepage and settlement of the embankment have been problems in the past.

D. Post Construction Changes

Post construction changes have included raising the dam by two feet and installing flashboards in 1876; modifying the spillway and sluiceway and raising the embankment in 1917; installing concrete cutoff walls, retaining walls and slab on the spillway in 1929; and plugging

the sluiceway with concrete and placing an earth and clay blanket on the upstream embankment slope in 1975.

E. Seismic Stability

This dam is located in Seismic Zone 1 and it is considered that the static stability is sufficient to withstand minor earthquake-induced dynamic forces. No studies or calculations have been made to confirm this assumption.

SECTION 7 - ASSESSMENT AND RECOMMENDATIONS

7.1 DAM ASSESSMENT

A. Safety

The visual inspection and the review of the construction drawings and records for modifications to the dam indicate that Lewis Lake Dam is in fair condition. The field inspection did not detect any signs of instability or seepage that would indicate an unsafe condition. Improved maintenance practices are required to ensure continued safe operation of the facility.

The hydrologic and hydraulic computations indicate that the combination of storage capacity and the spillway discharge capacity are able to handle 10 percent of the PMF. Failure of the dam due to overtopping will significantly increase the hazard to loss of life downstream of the dam. The spillway is considered to be seriously inadequate. The dam is therefore considered to be unsafe, non-emergency.

B. Adequacy of Information

The design and construction information contained in the files, combined with the visual inspection, are considered sufficiently adequate for making a reasonable assessment of this dam.

C. Urgency

The recommendations presented below should be implemented immediately.

D. Additional Studies

A detailed hydrologic and hydraulic analysis should be performed by a professional engineer, experienced in the design and construction of dams, to determine means for improving the capacity of the spillway.

7.2 RECOMMENDATIONS

In order to assure the continued satisfactory operation of this dam, the following recommendations are presented to the owner for immediate implementations.

1. That a detailed hydrologic and hydraulic engineering analysis be made by a professional engineer with experience in the design and construction of dams to determine means for improving the capacity of the spillway and reservoir system so that it will meet the requirements of the Commonwealth of Pennsylvania.

- 2. That all brush and trees be removed from the embankment slopes and in an area 10 feet beyond the downstream toe of the embankment and that a professional engineer be consulted regarding removal of the tree stumps and root systems.
- That the deteriorated areas on the downstream masonry portion of the dam be repaired.
- 4. That the deteriorated areas of the spillway abutments be repaired, and that the forebay area be cleared of obstructing fill.
- 5. That a formal surveillance and downstream warning system be developed for use during periods of high or prolonged rainfall.
- 6. That an operation and maintenance manual be prepared for guidance in the operation of the dam during normal and emergency conditions, and that a schedule be developed for the annual inspection of the dam and its appurtenant structures.

SUMMARY DESCRIPTION OF FLOOD HYDROGRAPH PACKAGE (HEC-1) DAM SAFETY VERSION

The hydrologic and hydraulic evaluation for this inspection report has employed computer techniques using the Corps of Engineers computer program identified as the Flood Hydrograph Package (HEC-1) Dam Safety Version.

The program has been designed to enable the user to perform two basic types of hydrologic analyses: (1) the evaluation of the overtopping potential of the dam, and (2) the capability to estimate the downstream hydrologic-hydraulic consequences resulting from assumed structural failures of the dam. A brief summary of the computation procedures typically used in the dam overtopping analysis is shown below.

- Development of an inflow hydrograph to the reservoir.
- Routing of the inflow hydrograph(s) through the reservoir to determine if the event(s) analyzed would overtop the dam.
- Routing of the outflow hydrograph(s) of the reservoir to desired downstream locations. The results provide the peak discharge and maximum stage of each routed hydrograph at the outlet of the reach.

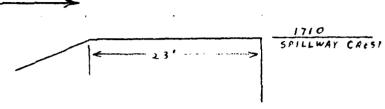

The output data provided by this program permits the comparison of downstream conditions just prior to a breach failure with that after a breach failure and the determination as to whether or not there is a significant increase in the hazard to loss of life as a result of such a failure.

The results of the studies conducted for this report are presented in Section 5.

For detailed information regarding this program refer to the Users Manual for the Flood Hydrograph Package (HEC-1) Dam Safety Version prepared by the Hydrologic Engineering Center, U.S. Army Corps of Engineers, Davis, California.

GEOLOGIC REPORT

GEOLOGIC REPORT

Bedrock - Dam and Reservoir

Formation Name: Catskill Formation, undifferentiated.

Lithology: The Catskill Formation consists of red shale interbedded with gray, cross-bedded sandstone, with some conglomerate, some red sandstone and gray to olive green shale.

Structure

The dam is located on the western limb of the Lackawanna Syncline. The strike of the beds here is nearly N-S and they dip 5° to 10° east.

Air photo fracture traces trend: N30°E, N10°W and N50°-55°W.

Overburden

The site is within the limits of Pleistocene glaciation and variable thicknesses of glacial till and outwash sediments are present in the area. No boring or test pit information is available.

Aquifer Characteristics

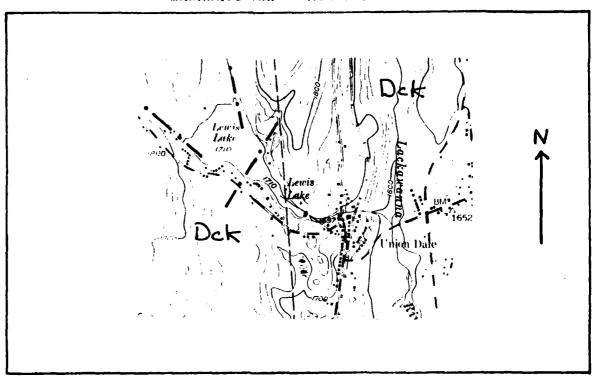

The rocks of the Catskill Formation are essentially impermeable and ground water movement is entirely along bedding planes and fractures. The most permeable aquifers in the area are the sands and gravel of the glacial outwash commonly found in the valleys.

Discussion

No plans are available for the original construction of this dam. It has been repaired and rebuilt several times. In 1929, a cutoff wall was added on the upstream face of the dam. It is reported to have been dug two feet into sand and hardpan. In 1930, "heavy leakage" was noted downstream from the dam. This leakage could have been either along permeable zones in the overburden, or along the N55°W fracture trace in the bedrock.

Sources of Information

- 1. Manuscript Geologic Map of the Forrest City Quadrangle in open file, Pa. Geologic Survey, Harrisburg, Pa.
- 2. Air Photographs, dated 1969. Scale 1:24,000.
- 3. Reports in file.
